Abstract

We propose a new Lagrangian describing $\mathcal{N} = 4$ superconformal field theory in three dimensions. This theory is believed to describe interacting field theory on the worldvolume of a M2-brane on an orbifold, and is obtained as a $\mathbb{Z}_2$ -quotient of the theory proposed by Bagger and Lambert. Despite unusual Chan-Paton structures, we can take $\mathbb{Z}_2$ -orbifold by using $SU(2) \times SU(2)$ bifundamental representations. We also analyze the moduli space of this theory and found three branches. With an assumption of a broken $U(1)$ symmetry, the moduli space is consistent with that of the D2-brane in the strong coupling limit of Type IIA string theory if the gauge group is $O(4)$. Our action has manifest $\mathbb{Z}_2$ -symmetry exchanging two $\mathbb{R}^4/\mathbb{Z}_2$'s in M-theory, and this suggests a new non-perturbative duality between a $O2^-$ -brane on orbifold $\mathbb{R}^4/\mathbb{Z}_2$ and a $O2^-$ -brane with D6-branes.

1 Introduction

In [1], motivated by early attempts [2,3], Bagger and Lambert proposed a new Lagrangian description of three-dimensional maximally supersymmetric ($\mathcal{N} = 8$) conformal field theory with manifest $SO(8)$ -symmetry (see also [4–6]). The theory is believed to be realized on the worldvolume of multiple M2-branes in M-theory, and many aspects of the theory has been explored recently [7–27].

Despite their success, we have so far only a single example of interacting field theories on the worldvolume of membranes, the so-called $\mathcal{A}_4$ -theory, which is interpreted as the worldvolume theory of two M2-branes in M-theory on $\mathbb{R}^8/\mathbb{Z}_2$ [12,13]. The original construction in [1] was based on new algebraic structures called Lie 3-algebras (and non-associative algebra), and there was hope for some time that there might exist many other Lie 3-algebras. However, it later was conjectured [18] and later proven [19,20] that only the $\mathcal{A}_4$ -theory is allowed in the framework of [4] under the condition of the positivity of the metric.⁴ Thus there is a pressing need to have more examples of Lagrangians describing theories on membranes.

In this paper we propose a new Lagrangian describing three-dimensional $\mathcal{N} = 4$ superconformal gauge theory. Our theory is obtained as a $\mathbb{Z}_2$ -quotient of Bagger-Lambert theory. This is non-trivial because the structure of Chan-Paton factor is unusual in Bagger-Lambert theory. Our study shows that $SU(2) \times SU(2)$ bifundamental representation [7], rather than the original $SO(4)$ notation [1], is essential for our purposes. Orbifolding also serves as a consistency check of the proposal that Bagger-Lambert theory describes theories on multiple M2-branes. For $\mathbb{Z}_2$ -orbifolded Bagger-Lambert theory, we find three branches of the moduli space. For Coulomb branches, we assumed the breaking of the $U(1)$ symmetry to its discrete subgroup $\mathbb{Z}_m$.⁵ The consistency with D2-branes picture [8] requires that such orbifolds should exist in the strong coupling limit and it should

⁴By abandoning positivity we can construct more examples of theories [17,18,23–25,27].

⁵Within the framework of the Bagger-Lambert theory, we cannot justify this assumption explicitly. In terms of ABJM theory [30], such breaking is naturally realized and orbifolded moduli space is studied [31].

describe M-theory on $\mathbb{R}^8/(\mathbb{Z}_2 \times \mathbb{Z}_2)$.⁶ Actually in the case of $m = 4$, the moduli space for the D2-brane with $O2^-$ -plane on the orbifold is consistent with that of $\mathbb{Z}_2$ -orbifolded Bagger-Lambert theory.

Another motivation comes from the recent work of [28]. Although our theory differs from that of [28], it also discusses three-dimensional Chern-Simons theories with $\mathcal{N} = 4$ supersymmetry, which is similar to our theory in many respects.

The organization of this article is as follows. We begin in section 2 with a brief summary of Bagger-Lambert theory in $SU(2) \times SU(2)$ bifundamental representation. Next we discuss in section 3 the $\mathbb{Z}_2$ -quotient of Bagger-Lambert theory. Then in section 4 we discuss the moduli space of theory. Section 5 is devoted to conclusions and discussions. In appendix A we summarize our notations of Γ -matrices.

2 Bagger-Lambert theory in bifundamental representation

In this section, in order to set up notations used in this paper, we briefly review the Bagger-Lambert theory [1] using the $SU(2) \times SU(2)$ bifundamental notation of [7]. Although the original paper [1] uses the $SO(4)$ notation, $SU(2) \times SU(2)$ notation is essential for our purposes.

The matter contents of the theory consists of eight scalar fields X^I ($I = 1, \dots, 8$), 11-dimensional Majorana fermion Ψ , and two gauge fields A_μ and $\hat{A}_\mu$. In bifundamental representation, the scalar fields X^I and fermionic fields Ψ are represented by a 2×2 matrix

$$X^I = \frac{1}{2} \begin{pmatrix} x_4^I + ix_3^I & x_2^I + ix_1^I \\ -x_2^I + ix_1^I & x_4^I - ix_3^I \end{pmatrix}, \quad \Psi = \frac{1}{2} \begin{pmatrix} \psi_4 + i\psi_3 & \psi_2 + i\psi_1 \\ -\psi_2 + i\psi_1 & \psi_4 - i\psi_3 \end{pmatrix}, \quad (2.1)$$

⁶This can also be written as $(\mathbb{R}^4/\mathbb{Z}_2) \times (\mathbb{R}^4/\mathbb{Z}_2)$, and thus we have manifest $\mathbb{Z}_2$ -symmetry exchanging two $\mathbb{R}^4/\mathbb{Z}_2$'s. In Type IIA language, this exchanges orientifold and $\mathbb{Z}_2$ orbifold, which is highly non-trivial. We will comment on the significance of this fact in the discussions.

and similarly for gauge fields

$$iA_\mu = \begin{pmatrix} ia^\mu & a_2^\mu + ia_1^\mu \\ -a_2^\mu + ia_1^\mu & -ia^\mu \end{pmatrix}, \quad i\hat{A}_\mu = \begin{pmatrix} i\hat{a}^\mu & \hat{a}_2^\mu + i\hat{a}_1^\mu \\ -\hat{a}_2^\mu + i\hat{a}_1^\mu & -i\hat{a}^\mu \end{pmatrix}. \quad (2.2)$$

Note that gauge fields are represented by traceless matrices, and their diagonal components are written as a^μ and $\hat{a}^\mu$, rather than a_3^μ and $\hat{a}_3^\mu$, respectively. The reality conditions for X_I 's are given by

$$X_{\alpha\dot{\beta}} = \epsilon_{\alpha\beta}\epsilon_{\dot{\beta}\dot{\alpha}} (X^\dagger)^{\dot{\alpha}\beta}, \quad (2.3)$$

and we also have the chirality condition for Ψ :

$$\Gamma^{012}\Psi = -\Psi. \quad (2.4)$$

In this notation, the Lagrangian of the Bagger-Lambert theory is given by

$$\begin{aligned} \mathcal{L} = & \text{Tr} \left(-(D^\mu X^I)^\dagger D_\mu X^I + i\bar{\Psi}^\dagger \Gamma^\mu D_\mu \Psi \right) \\ & + \text{Tr} \left(-\frac{2}{3}if\bar{\Psi}^\dagger \Gamma_{IJ}(X^I X^{J\dagger} \Psi + X^J \Psi^\dagger X^I + \Psi X^{I\dagger} X^J) - \frac{8}{3}f^2 X^{[I} X^{J\dagger} X^{K]} X^{K\dagger} X^J X^{I\dagger} \right) \\ & + \frac{1}{2f}\epsilon^{\mu\nu\lambda}\text{Tr} \left(A_\mu \partial_\nu A_\lambda + \frac{2}{3}iA_\mu A_\nu A_\lambda \right) - \frac{1}{2f}\epsilon^{\mu\nu\lambda}\text{Tr} \left(\hat{A}_\mu \partial_\nu \hat{A}_\lambda + \frac{2}{3}i\hat{A}_\mu \hat{A}_\nu \hat{A}_\lambda \right), \end{aligned} \quad (2.5)$$

where the covariant derivative is defined by

$$D_\mu X^I = \partial_\mu X^I + iA_\mu X^I - iX^I \hat{A}_\mu. \quad (2.6)$$

The supersymmetry transformations, under which the action is invariant, are given by

$$\delta X^I = i\bar{\epsilon}\Gamma^I\Psi, \quad (2.7)$$

$$\delta\Psi = D_\mu X^I \Gamma^\mu \Gamma^I \epsilon + \frac{2}{3}fX^I X^{J\dagger} X^K \Gamma^{IJK} \epsilon, \quad (2.8)$$

$$\delta A_\mu = f\bar{\epsilon}\Gamma_\mu \Gamma_I (X^I \Psi^\dagger - \Psi X^{I\dagger}), \quad (2.9)$$

$$\delta \hat{A}_\mu = f\bar{\epsilon}\Gamma_\mu \Gamma_I (\Psi^\dagger X^I - X^{I\dagger} \Psi), \quad (2.10)$$

where the spinor ϵ has the opposite chirality from Ψ :

$$\Gamma^{012}\epsilon = \epsilon. \quad (2.11)$$

Finally, in order to make the action invariant under large coordinate transformations, the parameter f should take the form

$$f = \frac{2\pi}{k}, \quad (2.12)$$

where the level k is a positive integer.

3 $\mathbb{Z}_2$ -action and its invariant sector

In this section we shall consider the $\mathbb{Z}_2$ -quotient of the Bagger-Lambert theory. We consider a discrete group $\mathbb{Z}_2$ acting on $\mathbb{R}^4$ in the $\mathbb{R}^8$ spatial directions transverse to M2-branes. We therefore decompose the eight scalar fields X^I ($I = 1, \dots, 8$) into Z^i ($i = 1, \dots, 4$) and Y^s ($s = 5, \dots, 8$). For each field our $\mathbb{Z}_2$ acts as follows:

$$Z^i \rightarrow -\gamma Z^i \gamma, \quad Y^s \rightarrow \gamma Y^s \gamma, \quad \Psi \rightarrow \Gamma^{1234} \gamma \Psi \gamma, \quad A_\mu \rightarrow \gamma A_\mu \gamma, \quad \hat{A}_\mu \rightarrow \gamma \hat{A}_\mu \gamma, \quad (3.1)$$

where γ is the regular representation of $\mathbb{Z}_2$ given by

$$\gamma = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (3.2)$$

This matrix γ is chosen so that it is consistent with the usual discussions of orbifolds [29] after the reduction to (the strong coupling limit of) D2-branes [8]. For the fermionic field Ψ the quotient action is realized as the $\Gamma^{1234} := \Gamma^1 \Gamma^2 \Gamma^3 \Gamma^4$ action. This corresponds to $\mathbb{Z}_2$ -action on $\mathbb{R}^4$ in $\mathbb{R}^8$, or π rotations in both 12 and 34 directions. The details are explained in the appendix.

For Z^i , Y^s and Ψ , the $\mathbb{Z}_2$ -quotient acts simply as multiplications by ± 1 on their diagonal (D) and off-diagonal (A) parts:

$$Z^i = Z_D^i + Z_A^i, \quad Y^s = Y_D^s + Y_A^s, \quad (3.3)$$

$$Z_D^i \rightarrow -Z_D^i, \quad Z_A^i \rightarrow Z_A^i, \quad Y_D^s \rightarrow Y_D^s, \quad Y_A^s \rightarrow -Y_A^s, \quad (3.4)$$

The fermionic fields should be further decomposed into Γ^{1234} eigenstates

$$\Psi = \Psi_D + \Psi_A = \Psi_{D+} + \Psi_{D-} + \Psi_{A+} + \Psi_{A-}, \quad (3.5)$$

$$\Psi_{D\pm} = P_\pm \Psi_D, \quad \Psi_{A\pm} = P_\pm \Psi_A, \quad \Psi_{D\pm} \rightarrow \pm \Psi_{D\pm}, \quad \Psi_{A\pm} \rightarrow \mp \Psi_{A\pm}, \quad (3.6)$$

where

$$P_{\pm} := \frac{1}{2}(1 \pm \Gamma^{1234}), \quad (3.7)$$

are the projectors onto $\Gamma^{1234} = \pm 1$.

3.1 Orbifold by $\mathbb{Z}_2$

Now we would like to prove that the $\mathbb{Z}_2$ -truncation as given by (3.1) gives a consistent theory with $\mathcal{N} = 4$ supersymmetry. To begin with, we discuss conditions under which $\mathcal{N} = 4$ supersymmetry is preserved after the $\mathbb{Z}_2$ -truncation.

We first decompose the fields into the two types: the $\mathbb{Z}_2$ -invariant fields

$$\mathcal{I} = \{Z_A, Y_D, \Psi_{D+}, \Psi_{A-}, A_D, \hat{A}_D\}, \quad (3.8)$$

and the other fields

$$\mathcal{N} = \{Z_D, Y_A, \Psi_{D-}, \Psi_{A+}, A_A, \hat{A}_A\}, \quad (3.9)$$

which will be projected out. The action of the orbifolded theory will be defined by

$$\tilde{S}(\mathcal{I}) = S(\mathcal{I}, \mathcal{N})|_{\mathcal{N}=0}, \quad (3.10)$$

from the original action $S(\mathcal{I}, \mathcal{N})$. Then the symmetry δ of the original theory will become also a symmetry of the orbifolded theory if the following condition is satisfied:

$$\delta \mathcal{N}|_{\mathcal{N}=0} = 0. \quad (3.11)$$

In such a case the symmetry of the orbifolded theory is generated by

$$\tilde{\delta} \mathcal{I} = \delta \mathcal{I}|_{\mathcal{N}=0}. \quad (3.12)$$

Indeed, from $\delta S = 0$ we can easily show that

$$\tilde{\delta} \tilde{S} = 0, \quad (3.13)$$

by expansion with respect to $\mathcal{N}$.

3.2 Compatibility of $\mathbb{Z}_2$ -orbifold with $\mathcal{N} = 4$ supersymmetry

Let us now examine condition (3.11) to ensure that we have remaining $\mathcal{N} = 4$ supersymmetry. From the definition of Z_D and γ , $Z_D := (Z + \gamma Z \gamma)/2$ and we find

$$\delta Z_D^i = \frac{1}{2} (\delta Z^i + \gamma (\delta Z^i) \gamma) = i \bar{\epsilon} \Gamma^i \Psi_D. \quad (3.14)$$

Thus,

$$\delta Z_D^i|_{\mathcal{N}=0} = i \bar{\epsilon} \Gamma^i \Psi_{D+} = i \bar{\epsilon} \Gamma^i P_+ \Psi_{D+} = i \bar{\epsilon} P_- \Gamma^i \Psi_{D+}, \quad (3.15)$$

and the (3.11) implies that the surviving supersymmetry should satisfy a chirality condition

$$P_- \epsilon = \frac{1}{2} (1 - \Gamma^{1234}) \epsilon = 0. \quad (3.16)$$

We also find

$$\delta Y_A^s|_{\mathcal{N}=0} = i \bar{\epsilon} \Gamma^s \Psi_{A-}, \quad (3.17)$$

which will vanish with (3.16).

The supersymmetry transformations for Ψ_{D-} and Ψ_{A+} are

$$\begin{aligned} \delta \Psi_{D-}|_{\mathcal{N}=0} &= \delta \left[P_- \Psi_{D-} \right] \Big|_{\mathcal{N}=0} \\ &= \left[(\partial_\mu Y_D^s + i A_{\mu D} Y_D^s - i Y_D^s \hat{A}_{\mu D}) \Gamma^\mu \Gamma^s + \frac{2}{3} f Y_D^s Y_D^{t\dagger} Y_D^u \Gamma^{stu} \right. \\ &\quad \left. + \frac{2}{3} f (Y_D^s Z_A^{i\dagger} Z_A^j + Z_A^j Y_D^{s\dagger} Z_A^i + Z_A^i Z_A^{j\dagger} Y_D^s) \Gamma^{ijs} \right] P_- \epsilon, \end{aligned} \quad (3.18)$$

$$\begin{aligned} \delta \Psi_{A+}|_{\mathcal{N}=0} &= \delta \left[P_+ \Psi_{A+} \right] \Big|_{\mathcal{N}=0} \\ &= \left[(\partial_\mu Z_A^i + i A_{\mu D} Z_A^i - i Z_A^i \hat{A}_{\mu D}) \Gamma^\mu \Gamma^i + \frac{2}{3} f Z_A^i Z_A^{j\dagger} Z_A^k \Gamma^{ijk} \right. \\ &\quad \left. + \frac{2}{3} f (Z_A^i Y_D^{s\dagger} Y_D^t + Y_D^t Z_A^{i\dagger} Y_D^s + Z_A^s Z_A^{t\dagger} Z_A^i) \Gamma^{sti} \right] P_- \epsilon. \end{aligned} \quad (3.19)$$

Thus we also find $\delta \mathcal{N}|_{\mathcal{N}=0} = 0$ for the fermionic fields if (3.16) is satisfied. It is also easy to check the compatibility condition for gauge fields. In this way we have proven that $\mathcal{N} = 4$ supersymmetry is preserved after the truncation.

3.3 The Lagrangian and its remaining $\mathcal{N} = 4$ supersymmetry

The surviving supersymmetry transformations are summarized as follows.

$$\tilde{\delta} Z_A^i = i\bar{\epsilon}\Gamma^i\Psi_{A-}, \quad (3.20)$$

$$\tilde{\delta} Y_D^s = i\bar{\epsilon}\Gamma^s\Psi_{D+}, \quad (3.21)$$

$$\begin{aligned} \tilde{\delta}\Psi_{D+} = & (\partial_\mu Y_D^s + iA_{\mu D}Y_D^s - iY_D^s\hat{A}_{\mu D})\Gamma^\mu\Gamma^s\epsilon \\ & + \frac{2}{3}f(Y_D^s Z_A^{i\dagger} Z_A^j + Z_A^j Y_D^{s\dagger} Z_A^i + Z_A^i Z_A^{j\dagger} Y_D^s)\Gamma^{ijs}\epsilon, \end{aligned} \quad (3.22)$$

$$\begin{aligned} \tilde{\delta}\Psi_{A-} = & (\partial_\mu Z_A^i + iA_{\mu D}Z_A^i - iZ_A^i\hat{A}_{\mu D})\Gamma^\mu\Gamma^i\epsilon \\ & + \frac{2}{3}f(Z_A^i Y_D^{s\dagger} Y_D^t + Y_D^t Z_A^{i\dagger} Y_D^s + Z_A^s Z_A^{t\dagger} Z_A^i)\Gamma^{sti}\epsilon, \end{aligned} \quad (3.23)$$

$$\tilde{\delta}A_{\mu D} = f\bar{\epsilon}\Gamma_\mu\Gamma_i(Z_A^i\Psi_{A-}^\dagger - \Psi_{A-}Z_A^{i\dagger}) + f\bar{\epsilon}\Gamma_\mu\Gamma_s(Y_D^s\Psi_{D+}^\dagger - \Psi_{D+}Y_D^{s\dagger}), \quad (3.24)$$

$$\tilde{\delta}\hat{A}_{\mu D} = f\bar{\epsilon}\Gamma_\mu\Gamma_i(\Psi_{A-}^\dagger Z_A^i - Z_A^i\Psi_{A-}) + f\bar{\epsilon}\Gamma_\mu\Gamma_s(\Psi_{D+}^\dagger Y_D^s - Y_D^s\Psi_{D+}). \quad (3.25)$$

In components, the supersymmetry transformations are

$$\tilde{\delta}z_1^i = i\bar{\epsilon}\Gamma^i\psi_1, \quad \tilde{\delta}z_2^i = i\bar{\epsilon}\Gamma^i\psi_2, \quad \tilde{\delta}y_3^s = i\bar{\epsilon}\Gamma^s\psi_3, \quad \tilde{\delta}y_4^s = i\bar{\epsilon}\Gamma^s\psi_4, \quad (3.26)$$

$$\tilde{\delta}\psi_1 = [\partial_\mu z_1^i + (a_\mu + \hat{a}_\mu)z_2^i]\Gamma^\mu\Gamma^s\epsilon + \frac{1}{2}fz_2^i(y_3^s y_4^t - y_3^t y_4^s)\Gamma^{sti}\epsilon, \quad (3.27)$$

$$\tilde{\delta}\psi_2 = [\partial_\mu z_2^i - (a_\mu + \hat{a}_\mu)z_1^i]\Gamma^\mu\Gamma^s\epsilon - \frac{1}{2}fz_1^i(y_3^s y_4^t - y_3^t y_4^s)\Gamma^{sti}\epsilon, \quad (3.28)$$

$$\tilde{\delta}\psi_3 = [\partial_\mu y_3^s + (a_\mu - \hat{a}_\mu)y_4^s]\Gamma^\mu\Gamma^s\epsilon + \frac{1}{2}fy_4^s(z_1^i z_2^j - z_2^i z_1^j)\Gamma^{ijs}\epsilon. \quad (3.29)$$

$$\tilde{\delta}\psi_4 = [\partial_\mu y_4^s - (a_\mu - \hat{a}_\mu)y_3^s]\Gamma^\mu\Gamma^s\epsilon - \frac{1}{2}fy_3^s(z_1^i z_2^j - z_2^i z_1^j)\Gamma^{ijs}\epsilon, \quad (3.30)$$

$$\tilde{\delta}a_\mu = \frac{i}{2}f\bar{\epsilon}\Gamma_\mu\Gamma_i(z_1^i\psi_2 - z_2^i\psi_1) + \frac{i}{2}f\bar{\epsilon}\Gamma_\mu\Gamma_s(y_3^s\psi_4 - y_4^s\psi_3), \quad (3.31)$$

$$\tilde{\delta}\hat{a}_\mu = -\frac{i}{2}f\bar{\epsilon}\Gamma_\mu\Gamma_i(z_1^i\psi_2 - z_2^i\psi_1) + \frac{i}{2}f\bar{\epsilon}\Gamma_\mu\Gamma_s(y_3^s\psi_4 - y_4^s\psi_3), \quad (3.32)$$

The Lagrangian for $\mathbb{Z}_2$ -orbifolded theory is ⁷

$$\begin{aligned}
\mathcal{L} = & \frac{1}{2} \text{Tr} [-(\mathcal{D}_D^\mu Y_D^s)^\dagger (\mathcal{D}_{\mu D} Y_D^s) - (\mathcal{D}_D^\mu Z_A^i)^\dagger (\mathcal{D}_{\mu D} Z_A^i)] \\
& + \frac{i}{2} \text{Tr} \left[\bar{\Psi}_{D+}^\dagger \Gamma^\mu \mathcal{D}_{\mu D} \Psi_{D+} + \bar{\Psi}_{A-}^\dagger \Gamma^\mu \mathcal{D}_{\mu D} \Psi_{A-} \right] \\
& - i f \text{Tr} \left[\bar{\Psi}_{D+}^\dagger \Gamma_{ij} \langle\langle Z_A^i, Z_A^{j\dagger}, \Psi_{D+} \rangle\rangle \right] - i f \text{Tr} \left[\bar{\Psi}_{A-}^\dagger \Gamma_{st} \langle\langle Y_D^s, Y_D^{t\dagger}, \Psi_{A-} \rangle\rangle \right] \\
& - i f \text{Tr} \left[\bar{\Psi}_{D+}^\dagger \Gamma_{si} \langle\langle Y_D^s, Z_A^{i\dagger}, \Psi_{A-} \rangle\rangle \right] - i f \text{Tr} \left[\bar{\Psi}_{A-}^\dagger \Gamma_{si} \langle\langle Y_D^s, Z_A^{i\dagger}, \Psi_{D+} \rangle\rangle \right] \\
& - \frac{1}{2} V(Z_A, Y_D) + \frac{1}{4f} \epsilon^{\mu\nu\rho} \text{Tr} \left[A_{\mu D} \partial_\nu A_{\rho D} - \hat{A}_{\mu D} \partial_\nu \hat{A}_{\rho D} \right], \tag{3.33}
\end{aligned}$$

where the covariant derivative $\mathcal{D}_D$ is defined by (when acting on Y_D^s , for example)

$$\mathcal{D}_{\mu D} Y_D^s = \partial_\mu Y_D^s + i A_{\mu D} Y_D^s - i Y_D^s \hat{A}_{\mu D}, \tag{3.34}$$

and the potential $V(Z_A, Y_D)$ is given by

$$\begin{aligned}
V(Z_A, Y_D) = & \frac{8}{3} f^2 \text{Tr} \left[\langle\langle Y_D^s, Z_A^{i\dagger}, Z_A^j \rangle\rangle Z_A^{j\dagger} Z_A^i Y_D^{s\dagger} + \langle\langle Z_A^j, Y_D^{s\dagger}, Z_A^i \rangle\rangle Z_A^{i\dagger} Y_D^s Z_A^{j\dagger} \right. \\
& + \langle\langle Z_A^i, Z_A^{j\dagger}, Y_D^s \rangle\rangle Y_D^{s\dagger} Z_A^j Z_A^{i\dagger} + \langle\langle Z_A^i, Y_D^{s\dagger}, Y_D^t \rangle\rangle Y_D^{t\dagger} Y_D^s Z_A^i \\
& \left. + \langle\langle Y_D^t, Z_A^{i\dagger}, Y_D^s \rangle\rangle Y_D^{s\dagger} Z_A^i Y_D^{t\dagger} + \langle\langle Y_D^s, Y_D^{t\dagger}, Z_A^i \rangle\rangle Z_A^{i\dagger} Y_D^t Y_D^{s\dagger} \right] \\
= & \frac{1}{4} f^2 \left[((y_3^s)^2 + (y_4^s)^2) (z_1^j z_2^i - z_1^i z_2^j)^2 + ((z_1^i)^2 + (z_2^i)^2) (y_3^t y_4^s - y_3^s y_4^t)^2 \right]. \tag{3.35}
\end{aligned}$$

In these equations $\langle\langle \rangle\rangle$ stands for summation over signed permutations with position of dagger fixed. For example,

$$\begin{aligned}
\langle\langle Z_A^i, Z_A^{j\dagger}, \Psi_{D+} \rangle\rangle := & \frac{1}{6} \left(Z_A^i Z_A^{j\dagger} \Psi_{D+} + Z_A^j \Psi_{D+}^\dagger Z_A^i + \Psi_{D+} Z_A^{i\dagger} Z_A^j \right. \\
& \left. - Z_A^j Z_A^{i\dagger} \Psi_{D+} - Z_A^i \Psi_{D+}^\dagger Z_A^j - \Psi_{D+} Z_A^{j\dagger} Z_A^i \right), \tag{3.36}
\end{aligned}$$

and

$$\begin{aligned}
\langle\langle Y_D^s, Z_A^{i\dagger}, Z_A^j \rangle\rangle := & \frac{1}{6} \left(Y_D^s Z_A^{i\dagger} Z_A^j + Z_A^j Y_D^{s\dagger} Z_A^i + Z_A^i Z_A^{j\dagger} Y_D^s \right. \\
& \left. - Z_A^i Y_D^{s\dagger} Z_A^j - Y_D^{s\dagger} Z_A^{j\dagger} Z_A^i - Z_A^j Z_A^{i\dagger} Y_D^s \right). \tag{3.37}
\end{aligned}$$

⁷We multiplied 1/2 factor to the Lagrangian in order to reproduce correct membrane tension in the Coulomb branch [31].

In terms of components, the Lagrangian is explicitly written down as follows.

$$\begin{aligned}
\mathcal{L} = & -\frac{1}{4} |[\partial_\mu + i(a_\mu - \hat{a}_\mu)](y_4^s + iy_3^s)|^2 - \frac{1}{4} |[\partial_\mu + i(a_\mu + \hat{a}_\mu)](z_2^i + iz_1^i)|^2 \\
& + \frac{i}{4} \left[\bar{\psi}_1 \not{\partial} \psi_1 + \bar{\psi}_2 \not{\partial} \psi_2 + \bar{\psi}_3 \not{\partial} \psi_3 + \bar{\psi}_4 \not{\partial} \psi_4 \right. \\
& + (a_\mu + \hat{a}_\mu) \bar{\psi}_1 \Gamma^\mu \psi_2 - (a_\mu + \hat{a}_\mu) \bar{\psi}_2 \Gamma^\mu \psi_1 + (a_\mu - \hat{a}_\mu) \bar{\psi}_3 \Gamma^\mu \psi_4 - (a_\mu - \hat{a}_\mu) \bar{\psi}_4 \Gamma^\mu \psi_3 \left. \right] \\
& + \frac{k'}{2\pi} \epsilon^{\mu\nu\rho} (a_\mu \partial_\nu a_\rho - \hat{a}_\mu \partial_\nu \hat{a}_\rho) \\

& + \frac{i}{8} f(y_4^s \bar{\psi}_3 - y_3^s \bar{\psi}_4) \Gamma_{si} (z_2^i \psi_1 - z_1^i \psi_2) + \frac{i}{8} f(z_2^i \bar{\psi}_1 - z_1^i \bar{\psi}_2) \Gamma_{is} (y_4^s \psi_3 - y_3^s \psi_4) \\
& - \frac{1}{8} f^2 [(y_3^s)^2 + (y_4^s)^2] (z_1^j z_2^i - z_1^i z_2^j)^2 + [(z_1^i)^2 + (z_2^i)^2] (y_3^t y_4^s - y_3^s y_4^t)^2. \tag{3.38}
\end{aligned}$$

The Chern-Simons gauge coupling k' of the $\mathbb{Z}_2$ orbifolded theory is related with that of the original action as⁸

$$k' = k/2. \tag{3.39}$$

3.4 Discrete symmetries of the Lagrangian

By $\mathbb{Z}_2$ -orbifolding, the gauge group of our theory is naively broken down to $U(1) \times U(1)$ generated by a_μ and $\hat{a}_\mu$. However, we have one discrete gauge symmetry $\mathbb{Z}_2$, which is generated by choosing $i\sigma_2$ from both $SU(2)$ of the original $SU(2) \times SU(2)$ gauge symmetry, and thus the gauge symmetry after the orbifolding is given by $U(1) \times U(1) \times \mathbb{Z}_2$. This $\mathbb{Z}_2$ symmetry acts as

$$y_3 \leftrightarrow -y_3, \quad z_1 \leftrightarrow -z_1, \quad \psi_3 \leftrightarrow \psi_3, \quad \psi_1 \leftrightarrow -\psi_1, \quad a_\mu \leftrightarrow -a_\mu, \quad \hat{a}_\mu \leftrightarrow -\hat{a}_\mu. \tag{3.40}$$

In addition to this gauged $\mathbb{Z}_2$ -symmetry, we have two more global $\mathbb{Z}_2$ -symmetries. The first is the parity invariance

$$A_\mu \leftrightarrow \hat{A}_\mu, \quad Y_D \leftrightarrow Y_D^\dagger, \quad Z_A \leftrightarrow Z_A^\dagger, \quad \Psi_{D+} \leftrightarrow \Gamma^1 \Psi_{D+}^\dagger, \quad \Psi_{A-} \leftrightarrow \Gamma^1 \Psi_{A-}^\dagger, \tag{3.41}$$

⁸The $\mathbb{Z}_2$ -orbifolding can only be performed in the case of even k [31].

which is essentially the same as the un-orbifolded case [3, 7].

We also have another discrete $\mathbb{Z}_2$ -symmetry, which does not exist in un-orbifolded theory:

$$y^s \leftrightarrow z^i, \quad \hat{A}_\mu \leftrightarrow -\hat{A}_\mu. \quad (3.42)$$

We will comment on the significance of this $\mathbb{Z}_2$ -symmetry later.

4 Moduli space

4.1 Moduli space of our theory

We will now study the moduli space of our model. In the previous section, we computed the potential $V(Z_A, Y_D)$ in (3.35). The solutions to $V(Z_A, Y_D) = 0$ are classified into the three phases.

$$(I) \quad z_1^i = 0, \quad z_2^i = 0, \quad (i = 1, 2, 3, 4), \quad (4.1)$$

$$(II) \quad y_3^s = 0, \quad y_4^s = 0, \quad (s = 5, 6, 7, 8), \quad (4.2)$$

$$(III) \quad y_3^s y_4^t = y_4^s y_3^t, \quad z_1^i z_2^j = z_2^i z_1^j. \quad (4.3)$$

The corresponding configurations of M2-branes are shown in Fig. 1. At generic point of moduli space (phase (III)), we have essentially a single M2-branes together with its three mirror images. When M2-branes lies at the fixed locus of $\mathbb{Z}_2$ (phase (I) and phase (II)), we have two M2-branes confined to fixed locus, together with their mirror images.

Phase (I): M2 at the fixed locus of the orbifold $\mathbb{Z}_2$

In this case, the solution for $V(Z_A, Y_D) = 0$ is

$$Z_A^i = 0, \quad Y_D^s = \begin{pmatrix} y^s & 0 \\ 0 & \bar{y}^s \end{pmatrix}, \quad (4.4)$$

where $y := y_4 + iy_3$.

To find the moduli space, we have to take into account $U(1) \times U(1) \times \mathbb{Z}_2$ gauge symmetry.

Figure 1: Sketch of solutions (I)-(III). M2-branes for phase (I), (II) and (III) are represented by blue, red and green dots, respectively.

Naively we can use $U(1) \times U(1)$ gauge symmetry and fix one of the phases of y^s 's. Here we simply assume without justification that the $U(1)$ gauge symmetry coupled to y is broken to a discrete subgroup $\mathbb{Z}_m$ where m is a some integer number.⁹ This $\mathbb{Z}_m$ acts on y^s as

$$y^s \rightarrow e^{2\pi ni/m} y^s. \quad (4.5)$$

We also have the gauged $\mathbb{Z}_2$ -symmetry (3.40)

$$y^s \rightarrow \bar{y}^s. \quad (4.6)$$

Combining these, we have the dihedral group $D_m = \mathbb{Z}_2 \ltimes \mathbb{Z}_m$ and the resulting moduli space is given by

$$\mathcal{M}^{(I),m} = (\mathbb{R}^4 \times \mathbb{R}^4)/D_m, \quad (4.7)$$

⁹There are subtleties in this argument. We cannot apply the mechanism in [12, 13] via the dual photon, because both of the $U(1) \times U(1)$ gauge fields $b_\mu := a_\mu - \hat{a}_\mu$ and $c_\mu := a_\mu + \hat{a}_\mu$ couple to the scalar fields in the action (3.38) and the auxiliary fields cannot be introduced. Within the framework of the Bagger-Lambert theory, we could not justify this point explicitly. But we expect such mechanism happens, because the matching of the moduli spaces of M-theory and Type IIA for the each branches should be realized.

and the unbroken gauge symmetry is $U(1)_V$, which is generated by $a_\mu + \hat{a}_\mu$. In the special case $m = 4$, we have

$$\mathcal{M}^{(I), m=4} = \frac{(\mathbb{R}^4/\mathbb{Z}_2) \times (\mathbb{R}^4/\mathbb{Z}_2)}{\mathbb{Z}_2}. \quad (4.8)$$

Phase (II): M2 at the other fixed locus

In this case, the solution for $V(Z_A, Y_D) = 0$ is

$$Y_D^s = 0, \quad Z_A^i = \begin{pmatrix} 0 & z^i \\ -\bar{z}^i & 0 \end{pmatrix}, \quad (4.9)$$

where $z := z_2 + iz_1$. Due to the presence of $\mathbb{Z}_2$ -symmetry (3.42), we find that the moduli space for phase (II) is isomorphic to that of phase (I):

$$\mathcal{M}^{(I), m} \simeq \mathcal{M}^{(II), m}. \quad (4.10)$$

The unbroken gauge symmetry is $U(1)_A$,¹⁰ which is generated by $a_\mu - \hat{a}_\mu$.

Phase (III): Generic point in moduli space:

In this case, the general solution for the $V(Z_A, Y_D) = 0$ is

$$Z_A^i = \begin{pmatrix} 0 & z_0^i e^{i\phi} \\ -z_0^i e^{-i\phi} & 0 \end{pmatrix}, \quad Y_D^s = \begin{pmatrix} y_0^s e^{i\theta} & 0 \\ 0 & y_0^s e^{-i\theta} \end{pmatrix}, \quad (4.11)$$

where z_0^i and y_0^s are real. There are discrete $\mathbb{Z}_2 \times \mathbb{Z}_2$ symmetries

$$(z^i, \phi) \rightarrow (-z^i, \phi + \pi), \quad (y^s, \theta) \rightarrow (-y^s, \theta + \pi). \quad (4.12)$$

By using $U(1) \times U(1)$ symmetry we can fix the phases θ and ϕ to be zero.

In this vacuum there are no residual symmetries in gauge fields in contrast to phases (I) and (II). Actually the action for scalars and gauge fields are given by

$$\begin{aligned} \mathcal{L}_g = & -\frac{1}{4} |\partial_\mu y^s + i(a_\mu - \hat{a}_\mu) y^s|^2 - \frac{1}{4} |\partial_\mu z^i + i(a_\mu + \hat{a}_\mu) z^i|^2 \\ & + \frac{k'}{2\pi} \epsilon^{\mu\nu\rho} (a_\mu \partial_\nu a_\rho - \hat{a}_\mu \partial_\nu \hat{a}_\rho). \end{aligned} \quad (4.13)$$

¹⁰As a special point of phase (I) and (II), i.e. when y^s and z^i are all equal to zero, the unbroken gauge group is enhanced to $U(1)_V \times U(1)_A$.

For the generic point in the moduli space $y^s \neq 0$, $z^i \neq 0$, the minimum of this action is realized for $a_\mu = \hat{a}_\mu = 0$. Then the moduli space for this case consists only of scalar fields.

As a result we find the moduli space $\mathcal{M}^{(III)}$ for phase (III) is

$$\mathcal{M}^{(III)} = (\mathbb{R}^4/\mathbb{Z}_2) \times (\mathbb{R}^4/\mathbb{Z}_2). \quad (4.14)$$

This result is independent of k' .

4.2 Comparison with Type IIA moduli space

We are now in a position to compare the moduli space of our theory obtained so far to that of D2-branes in the strong coupling limit of Type IIA string theory. If our theory really describes theories on membranes, then these two moduli spaces should match. This serves as a good consistency check of Bagger-Lambert theory and our $\mathbb{Z}_2$ -orbifolding procedure. At first sight the analyses in M-theory and Type IIA look similar, but at closer inspections of field contents in two theories are largely different and the match is far from trivial.

The discussion of $\mathbb{Z}_2$ -orbifolding of $O(4)$ gauge theory¹¹ is analogous to the discussion above of the M-theory case. Using 4×4 matrix representations, take the regular representation γ to be

$$\gamma = \left(\begin{array}{cc|cc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ \hline 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{array} \right), \quad (4.15)$$

and consider $\mathbb{Z}_2$ -action as in (3.1):

$$Z^i \rightarrow -\gamma Z^i \gamma, \quad Y^{s'} \rightarrow \gamma Y^{s'} \gamma, \quad \Psi \rightarrow \Gamma^{1234} \gamma \Psi \gamma, \quad A_\mu \rightarrow \gamma A_\mu \gamma, \quad (4.16)$$

where the seven scalars are decomposed into four scalars Z^i ($i = 1, 2, 3, 4$) and $Y^{s'}$ ($s' = 5, 6, 7$). Here we are taking the M-theory direction to be the 8-direction. By this $\mathbb{Z}_2$ -action, the remaining fields are $Y_D^{s'}, Z_A^i, \Psi_{D+}, \Psi_{A-}$ and $A_{D\mu}$, where suffixes D (and A)

¹¹In [12, 13] the Type IIA string theory configuration corresponding to the un-orbifolded theory with $k = 1$ is discussed. Via Higgsing, they found that the Type IIA moduli space for $k = 1$ describes the configuration of one $O2^-$ -plane and two D2-branes (together with their mirror images). The resulting worldvolume theory is $SO(4)$ gauge theory rather than $O(4)$. Actually the $O(4)$ gauge theory is found naturally in [30, 32].

represents 2×2 block diagonal (block off-diagonal) components. For example, gauge field $A_{D\mu}$ after the $\mathbb{Z}_2$ -truncation is represented by

$$A_{D\mu} = \left(\begin{array}{cc|cc} 0 & a_\mu^A & 0 & 0 \\ -a_\mu^A & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & a_\mu^V \\ 0 & 0 & -a_\mu^V & 0 \end{array} \right), \quad (4.17)$$

where (up to irrelevant coefficients) in our previous notation in the M-theory, we have written $a_\mu^V = a_\mu + \hat{a}_\mu$ and $a_\mu^A = a_\mu - \hat{a}_\mu$. After orbifolding, the gauge symmetry is given by $SO(2) \times SO(2) \simeq U(1) \times U(1)$, plus discrete gauge symmetries which we will comment on in a moment.

The moduli space of this theory again consists of three branches:

$$(i) : Y^{s'} \neq 0, Z^i = 0, \quad (4.18)$$

$$(ii) : Y^{s'} = 0, Z^i \neq 0, \quad (4.19)$$

$$(iii) : Y^{s'} \neq 0, Z^i \neq 0. \quad (4.20)$$

The corresponding configurations of D2-branes are almost the same as in M-theory case, namely as in Figure 1. The only difference is that we have only three $Y^{s'}$ directions, not four. We now analyze each phase in detail.

Phase (i): D2 at the fixed locus of the orbifold $\mathbb{Z}_2$

In this phase, only the $Y^{s'}$'s take non-zero value:

$$Y^{s'} = \left(\begin{array}{cc|cc} 0 & \alpha^{s'} & 0 & 0 \\ -\alpha^{s'} & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & \beta^{s'} \\ 0 & 0 & -\beta^{s'} & 0 \end{array} \right), \quad Z^i = 0, \quad (4.21)$$

where $\alpha^{s'}$ and $\beta^{s'}$ are arbitrary real numbers.

At this phase, the gauge symmetry $U(1)_V \times U(1)_A$ is completely preserved. This means in addition to scalars $\alpha^{s'}$ and $\beta^{s'}$, we have two periodic parameters σ_V and σ_A obtained by dualizing two gauge fields a_μ^A and a_μ^V . Thus we have $\mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{S}^1 \times \mathbb{S}^1$, parametrized

by $\alpha^{s'}, \beta^{s'}, \sigma_V$ and σ_A . However, we still have to take care of discrete symmetries of $O(4)$. Namely, two discrete symmetries in $SO(4)$

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad (4.22)$$

gives two $\mathbb{Z}_2$ -symmetries

$$\alpha^{s'} \rightarrow -\alpha^{s'}, \quad \beta^{s'} \rightarrow -\beta^{s'}, \quad a_\mu^A \rightarrow -a_\mu^A, \quad \sigma_A \rightarrow -\sigma_A, \quad a_\mu^V \rightarrow -a_\mu^V, \quad \sigma_V \rightarrow -\sigma_V, \quad (4.23)$$

and

$$\alpha^{s'} \rightarrow \beta^{s'}, \quad a_\mu^V \rightarrow a_\mu^A, \quad \sigma_V \rightarrow \sigma_A, \quad (4.24)$$

while keeping other fields fixed. Further, discrete symmetry in $O(4)$

$$\begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad (4.25)$$

gives one more $\mathbb{Z}_2$ -symmetry

$$\alpha^{s'} \rightarrow -\alpha^{s'}, \quad a_\mu^A \rightarrow -a_\mu^A, \quad \sigma_A \rightarrow -\sigma_A. \quad (4.26)$$

Combining all these three discrete $\mathbb{Z}_2$, the moduli space is given by

$$\mathcal{M}^{(i)} = \frac{((\mathbb{R}^3 \times \mathbb{S}^1)/\mathbb{Z}_2) \times ((\mathbb{R}^3 \times \mathbb{S}^1)/\mathbb{Z}_2)}{\mathbb{Z}_2} \quad (4.27)$$

When the coupling goes to infinite, $\mathbb{S}^1$ decompactify¹² and we have the correct moduli space $((\mathbb{R}^4/\mathbb{Z}_2) \times (\mathbb{R}^4/\mathbb{Z}_2))/\mathbb{Z}_2$, as expected¹³:

$$\mathcal{M}^{(i)} \rightarrow \mathcal{M}^{(I), m=4}, \quad \text{as } g_{YM} \rightarrow \infty. \quad (4.28)$$

¹²According to the interpretation of [12, 13], expectation values of X_I 's represent the location of M2-brane in the uncompactified M-theory, not the compactification radius as in [8].

¹³If we use $SO(4)$ gauge group rather than $O(4)$, one $\mathbb{Z}_2$ factor is unnecessary and the moduli space becomes $(\mathbb{R}^4/\mathbb{Z}_2)^2$. This is consistent with the phase (I) moduli space of M-theory with $m = 4$. Although the breaking of $U(1)_A$ symmetry in M-theory could not be explained in the context of the orbifolding for the Bagger-Lambert theory, this fact will support our assumption. The same discussion applies to phase (II) and (ii) as well. In phase (iii), however, if we use $SO(4)$ gauge group we have branches (as we will see in (4.33)), and the moduli space seemingly does not match with that of phase (III).

Phase (ii): D2 on the orientifold

In M-theory, moduli of Phase (I) and that of Phase (II) are automatically isomorphic, due to the presence of discrete $\mathbb{Z}_2$ -symmetry (3.42). It is non-trivial, however, to verify the corresponding fact for Type IIA, because orbifold and orientifold are different in Type IIA.

In phase (ii), the scalars are given by

$$Y^{s'} = 0, \quad Z^i = \left(\begin{array}{cc|cc} 0 & 0 & \gamma^i & 0 \\ 0 & 0 & 0 & \delta^i \\ \hline -\gamma^i & 0 & 0 & 0 \\ 0 & -\delta^i & 0 & 0 \end{array} \right), \quad (4.29)$$

where γ^i and δ^i are real numbers. The form of Z^i 's are chosen so that Z^i 's mutually commute, thereby minimizing the potential. On this phase, the gauge symmetry is completely broken¹⁴ and we have no scalars coming from the gauge field. By taking care of discrete gauge transformations (4.22) and (4.25), we have three $\mathbb{Z}_2$ -identifications (1) $\gamma^i \leftrightarrow -\gamma^i, \delta^i \leftrightarrow \delta^i$, (2) $\gamma^i \leftrightarrow \gamma^i, \delta^i \leftrightarrow -\delta^i$, (3) $\gamma^i \leftrightarrow \delta^i$, and thus we have the moduli space

$$\mathcal{M}^{(ii)} = \frac{(\mathbb{R}^4/\mathbb{Z}_2) \times (\mathbb{R}^4/\mathbb{Z}_2)}{\mathbb{Z}_2} = \mathcal{M}^{(II), m=4}. \quad (4.30)$$

In this case, the moduli space coincides with that of M-theory even before taking the strong gauge coupling limit.

Phase (iii): D2 at the generic point of the moduli space

In this phase, both $Y^{s'}$'s and Z^a 's take non-zero value:

$$Y^{s'} = \left(\begin{array}{cc|cc} 0 & \alpha^{s'} & 0 & 0 \\ -\alpha^{s'} & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & \beta^{s'} \\ 0 & 0 & -\beta^{s'} & 0 \end{array} \right), \quad Z^i = \left(\begin{array}{cc|cc} 0 & 0 & \gamma^i & 0 \\ 0 & 0 & 0 & \delta^i \\ \hline -\gamma^i & 0 & 0 & 0 \\ 0 & -\delta^i & 0 & 0 \end{array} \right), \quad (4.31)$$

¹⁴Gauge symmetry $U(1)_V$ (resp. $U(1)_A$) is restored, however, when $\gamma^i = \delta^i$ (resp. $\gamma^i = -\delta^i$).

In order to minimize the potential, these matrices should commute, giving us the condition

$$\alpha^{s'} \gamma^i = \beta^{s'} \delta^i, \quad \alpha^{s'} \delta^i = \beta^{s'} \gamma^i, \quad (4.32)$$

which given us

$$\alpha^{s'} = \pm \beta^{s'}, \quad \gamma^i = \pm \delta^i, \quad (4.33)$$

where we should take the same sign for two equations in (4.33). In this phase, the unbroken gauge symmetry is given by $U(1)_V$ (resp. $U(1)_A$) when we take the plus (resp. minus) sign in (4.33). This contributes one extra scalar σ_V (resp. σ_A) to the moduli space.

Again by taking care of discrete gauge symmetries, the two choices of $\pm$ in (4.33) are identified by (4.25), and we have in addition two discrete gauge symmetries

$$\alpha^{s'} \rightarrow -\alpha^{s'}, \quad \sigma_V \rightarrow -\sigma_V, \quad (4.34)$$

and

$$\delta^i \rightarrow -\delta^i. \quad (4.35)$$

We thus have

$$\mathcal{M}^{(iii)} = \frac{\mathbb{R}^4}{\mathbb{Z}_2} \times \frac{\mathbb{R}^3 \times \mathbb{S}^1}{\mathbb{Z}_2}. \quad (4.36)$$

When we go to the strong gauge coupling limit, $\mathbb{S}^1$ again decompactify and we thus have the moduli space $(\mathbb{R}^4/\mathbb{Z}_2) \times (\mathbb{R}^4/\mathbb{Z}_2)$, which is consistent with the M-theory analysis in (4.14).

5 Conclusions and Discussions

In this paper, we have proposed a new Lagrangian describing $\mathcal{N} = 4$ superconformal field theory in three dimensions. This Lagrangian is likely to describe interacting field

theory on the worldvolume of a M2-brane placed on an orbifold $\mathbb{R}^8/(\mathbb{Z}_2 \times \mathbb{Z}_2)$, and is obtained as a $\mathbb{Z}_2$ -orbifold of Bagger-Lambert theory in the $SU(2) \times SU(2)$ bifundamental representations.

We also analyzed the moduli space of our theory and found three branches. In the analysis of the Phase (I) and (II), we assumed some mechanism to make one of $U(1)$ gauge symmetry be broken to the discrete subgroup $\mathbb{Z}_m$. Within the framework of the Bagger-Lambert theory, we could not justify this mechanism explicitly. But under this assumption, the matching of the moduli spaces of M-theory and Type IIA theory for each branches can be found especially for $m = 4$ in highly non-trivial way. In this discussion, the moduli space for the Type IIA theory is given by the $\mathbb{Z}_2$ -orbifold of $O(4)$ gauge theory, rather than $SO(4)$ as in [12, 13]. Conversely speaking, the M2-brane theory on the $\mathbb{Z}_2$ -orbifold should be defined as the strong coupling limit of the Type IIA brane configuration on $\mathbb{Z}_2$ -orbifold, then the matching of each branches of moduli space supports our assumption and analysis in M-theory.

The interesting feature of our Lagrangian is the existence of $\mathbb{Z}_2$ -symmetry (3.42), which exchanges two $\mathbb{Z}_2$ -actions. In M-theory viewpoint this is natural and simplify exchanges two $\mathbb{Z}_2$ -actions, but in Type IIA language this exchanges orbifold with orientifold, which is highly non-trivial. In our discussion, we have deleted 8-direction (i.e. one of the Y^s -directions) to obtain $\mathbb{Z}_2$ -orbifold of D2-O2⁻ system. If we instead reduce along Z^i -directions, then we should have D6-D2-O2⁻ system without $\mathbb{Z}_2$ -orbifold. Now the symmetry (3.42) implies a new duality between $\mathbb{Z}_2$ -orbifold of O2⁻ and D6-O2⁻. We call this new non-perturbative duality “O-duality”.¹⁵ ¹⁶ The existence of orientifold is crucial for the existence of this duality. As a possible check of this proposal, our moduli space in phase (I) should match with the instanton moduli space of $SU(2)$ -instanton placed at an $\mathbb{Z}_2$ -orbifold, and it would be interesting to explicitly verify this.

Finally, in this paper we have concentrated on a single example of $\mathbb{Z}_2$ acting on $\mathbb{R}^4$.

¹⁵O stands for orientifold and orbifold, and also for gauge groups $O(N)$.

¹⁶The existence of duality is not limited to BLG theory and exists also in the orbifold of $U(2) \times U(2)$ ABJM theory [30], as discussed in section 4.2 of [31]. In the notation of the paper, the $\mathbb{Z}_2$ -symmetry exchanges Z^1, W^1 and Z^2, W^2 .

We can consider more examples by considering $\mathbb{Z}_2$ acting on $\mathbb{R}^2$, $\mathbb{R}^6$ and $\mathbb{R}^8$, for example, and it would be interesting to study them.

A Notations of Γ -matrices

In this appendix, we explain the origin of the Γ^{1234} factor in (3.1).

For our purpose, it is convenient to use the following explicit representations of the 11-dimensional Γ -matrices:

$$\begin{aligned}
\Gamma^1 &= 1 \times \tau_3 \times \epsilon \times \epsilon \times \tau_3, & \Gamma^2 &= \tau_1 \times \epsilon \times 1 \times \epsilon \times \tau_3, \\
\Gamma^3 &= \tau_3 \times \epsilon \times 1 \times \epsilon \times \tau_3, & \Gamma^4 &= \epsilon \times 1 \times \tau_1 \times \epsilon \times \tau_3, \\
\Gamma^5 &= 1 \times \tau_1 \times \epsilon \times \epsilon \times \tau_3, & \Gamma^6 &= \epsilon \times \epsilon \times \epsilon \times \epsilon \times \tau_3, \\
\Gamma^7 &= \epsilon \times 1 \times \tau_3 \times \epsilon \times \tau_3, & \Gamma^8 &= 1 \times 1 \times 1 \times \tau_1 \times \tau_3, \\
\Gamma^9 &= 1 \times 1 \times 1 \times 1 \times \tau_1, & \Gamma^0 &= 1 \times 1 \times 1 \times 1 \times \epsilon, \\
\Gamma^{10} &= \Gamma^0 \Gamma^1 \dots \Gamma^9 = 1 \times 1 \times 1 \times \tau_3 \times \tau_3
\end{aligned} \tag{A.1}$$

We want to study the effect of reflections ($Z^i \rightarrow -Z^i$, $Y^s \rightarrow Y^s$) on the fermion Ψ . This $\mathbb{Z}_2$ -action is equivalent to π rotations in 12-planes and 34-planes. In the representation of (A.1), generators of rotations in 12- and 34- planes are given by

$$\Sigma_{12} = \frac{-i}{4}[\Gamma^1, \Gamma^2], \quad \Sigma_{34} = \frac{-i}{4}[\Gamma^3, \Gamma^4], \tag{A.2}$$

with

$$\frac{1}{2}[\Gamma^1, \Gamma^2] = \epsilon \times 1 \times 1 \times 1 \times 1, \quad \frac{1}{2}[\Gamma^3, \Gamma^4] = 1 \times 1 \times \epsilon \times 1 \times 1. \quad (\text{A.3})$$

By using the identity

$$\exp\left(\frac{\pi}{2}\epsilon\right) = \cos\left(\frac{\pi}{2}\right) \mathbf{1} + \sin\left(\frac{\pi}{2}\right) \epsilon = \epsilon, \quad (\text{A.4})$$

we obtain

$$\exp(i\pi(\Sigma_{12} + \Sigma_{34})) = \epsilon \times 1 \times \epsilon \times 1 \times 1 = \Gamma^1 \Gamma^2 \Gamma^3 \Gamma^4 = \Gamma^{1234}, \quad (\text{A.5})$$

and we find Γ^{1234} factor in (3.1), as expected. Note that the final result is independent of specific representations of Γ -matrices we used above.
